

ELEMENTARY BOUNDS ON DIGITAL SUMS OF POWERS, FACTORIALS, AND LCMS

SHREYANSH JAISWAL AND DAVID G. RADCLIFFE

ABSTRACT. We prove lower bounds on digital sums of powers, multiples of powers, factorials, and the least common multiple of $\{1, \dots, n\}$, using only elementary number theory.

1. INTRODUCTION

This expository article establishes lower bounds on digital sums of powers, multiples of powers, factorials, and the least common multiple of $\{1, \dots, n\}$, using only elementary number theory.

We were inspired by the following problem, which was posed and solved by Waclaw Sierpiński [8, Problem 209]:

Prove that the sum of digits of the number 2^n (in decimal system) increases to infinity with n .

The reader is urged to attempt this problem on their own before proceeding. Note that it is not enough to prove that the sum of digits of 2^n is unbounded, since the sequence is not monotonic.

Consider the sequence of powers of 2 (sequence A000079 in the OEIS):

$$1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, \dots$$

This sequence grows very rapidly. Now, let us define another sequence, by adding the decimal digits of each power of 2. For example, 16 becomes $1 + 6 = 7$, and 32 becomes $3 + 2 = 5$. The first few terms of this new sequence (A001370) are listed below.

$$1, 2, 4, 8, 7, 5, 10, 11, 13, 8, 7, \dots$$

Date: December 10, 2025.

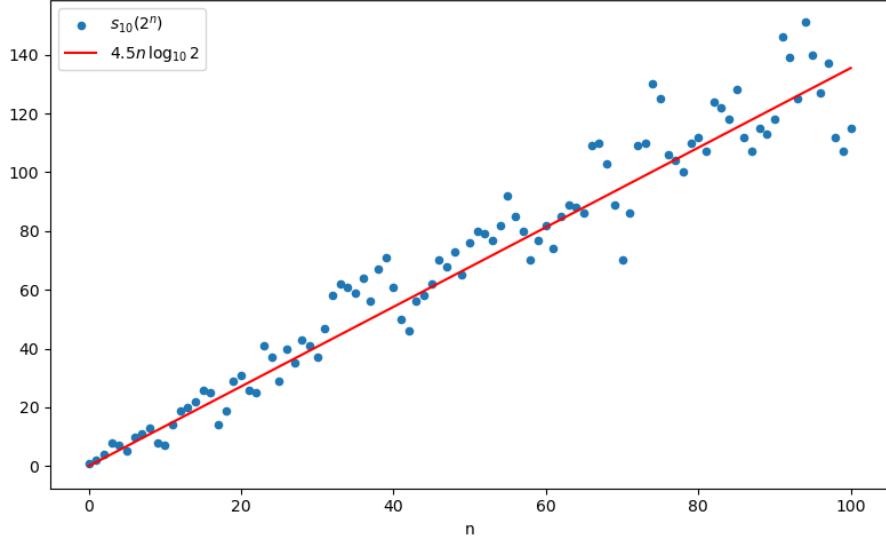

FIGURE 1. Scatter plot of the digital sum of 2^n for $n \leq 100$ together with the conjectured linear approximation.

This new sequence grows much more slowly, and it is not monotonic. Nevertheless, it is reasonable to conjecture that it tends to infinity. Indeed, one might guess that the sum of the decimal digits of 2^n is approximately equal to $4.5n \log_{10} 2$, since 2^n has $\lfloor n \log_{10} 2 \rfloor + 1$ decimal digits, and the digits seem to be approximately uniformly distributed among $0, 1, 2, \dots, 9$. However, this stronger conjecture remains to be proved. See Figure 1.

We prove in Section 3 that the digital sum of 2^n is greater than $\log_4 n$ for all $n \geq 1$. But first, we introduce some notation.

2. NOTATION AND TERMINOLOGY

For integers $n \geq 0$ and $b \geq 2$, the *base- b expansion* of n is the unique representation of the form

$$n = \sum_{i=0}^{\infty} d_i b^i, \quad d_i \in \{0, 1, \dots, b-1\}.$$

The integers d_i are the *base- b* digits of n ; all but finitely many of these digits are zero.

For an integer $b \geq 2$, we write $s_b(n)$ for the sum of the base- b digits of n , and $c_b(n)$ for the number of nonzero digits in that expansion. These functions are equivalent

up to a constant factor, since $c_b(n) \leq s_b(n) \leq (b-1)c_b(n)$ for all n and b ; so we focus on $c_b(n)$.

The function s_b is *subadditive*: $s_b(m+n) \leq s_b(m) + s_b(n)$ for all positive integers m and n . Equality holds if no carries occur in the digitwise addition of m and n . Otherwise, each carry reduces the digital sum by $b-1$. The function c_b is likewise subadditive.

For a prime p , $\nu_p(n)$ denotes the exponent of p in the prime factorization of n . If p does not divide n then $\nu_p(n) = 0$. The function ν_p is *completely additive*: $\nu_p(mn) = \nu_p(m) + \nu_p(n)$ for all positive integers m and n .

Recall that the *floor* of x , denoted $\lfloor x \rfloor$, is the greatest integer n such that $n \leq x$. The *ceiling* of x , denoted $\lceil x \rceil$, is the least integer n such that $n \geq x$.

We use Bachmann-Landau-Knuth notations [3] to describe the approximate size of functions. Let f and g be real-valued functions defined on a domain D , usually the set of positive integers.

One writes

$$f(n) = O(g(n))$$

if there exists a positive real number C such that

$$|f(n)| \leq Cg(n) \quad \text{for all } n \in D.$$

The notation

$$f(n) = o(g(n))$$

means that

$$\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 0.$$

In particular, $O(1)$ denotes a bounded function, and $o(1)$ denotes a function that tends to 0 as $n \rightarrow \infty$.

Finally,

$$f(n) \asymp g(n)$$

means that there exist positive real numbers C and C' such that

$$Cg(n) < |f(n)| < C'g(n) \quad \text{for all } n \in D.$$

$$\begin{aligned}
 2^0 &= & 1 \\
 2^4 &= & 16 \\
 2^{14} &= & 1\,638\,4 \\
 2^{47} &= & 1\,407\,374\,883\,5\,532\,8 \\
 2^{157} &= 1\,826\,877\,046\,663\,628\,647\,754\,606\,040\,895\,353\,774\,569\,915\,6\,787\,2
 \end{aligned}$$

FIGURE 2. Digits of 2^n subdivided into blocks. Each block contains at least one nonzero digit.

3. DIGITAL SUMS OF POWERS OF TWO

We present an informal proof that $c_{10}(2^n)$ tends to infinity as $n \rightarrow \infty$. See [5] for an alternative approach.

Let n be a positive integer, and write the decimal expansion of 2^n as $2^n = \sum_{i=0}^{\infty} d_i 10^i$, where $d_i \in \{0, \dots, 9\}$ and $d_i = 0$ for all but finitely many terms. Note that the final digit d_0 of 2^n cannot be zero, since 2^n is not divisible by 10.

If $2^n > 10$, then 2^n is divisible by 16; so $2^n \bmod 10^4$, the number formed by the last four digits of 2^n , is also divisible by 16. If the first three of these digits were zero, then $2^n \bmod 10^4$ would be less than 10, which is impossible. So at least one of the digits d_1, d_2, d_3 is nonzero.

If $2^n > 10^4$, then 2^n is divisible by 2^{14} ; so $2^n \bmod 10^{14}$, the number formed by the last 14 digits of 2^n , is also divisible by 2^{14} . If the first 10 of these digits were zero, then $2^n \bmod 10^{14}$ would be less than 10^4 , which is impossible. So at least one of the digits d_4, d_5, \dots, d_{13} is nonzero.

We can continue in this way, finding longer and longer non-overlapping blocks of digits, each containing at least one nonzero digit, as illustrated in Figure 2. This proves that $c_{10}(2^n)$ tends to infinity as $n \rightarrow \infty$.

Let us formalize this argument.

Theorem 1. *Let $(e(k))_{k \geq 1}$ be a sequence of integers such that $e(1) \geq 1$ and $2^{e(k)} > 10^{e(k-1)}$ for all $k \geq 2$. If n is a positive integer that is divisible by $2^{e(k)}$ but not divisible by 10, then $c_{10}(n) \geq k$.*

Proof. We argue by induction on k . The case $k = 1$ is immediate, since any positive integer has at least one nonzero digit.

Assume now that $k \geq 2$, and that the statement holds for $k - 1$. Let n be a positive integer divisible by $2^{e(k)}$ but not by 10. Apply the division algorithm to write

$$n = 10^{e(k-1)}q + r, \quad 0 \leq r < 10^{e(k-1)},$$

for integers q, r .

Because $n \geq 2^{e(k)} > 10^{e(k-1)}$ by hypothesis, the quotient satisfies $q \geq 1$.

Next, both n and $10^{e(k-1)}q$ are divisible by $2^{e(k-1)}$, hence their difference

$$r = n - 10^{e(k-1)}q$$

is also divisible by $2^{e(k-1)}$.

Moreover, r is not divisible by 10, since n is not divisible by 10.

Therefore, $c_{10}(r) \geq k - 1$ by the induction hypothesis.

Finally, the decimal expansion of n is obtained by concatenating the decimal expansion of q with the (possibly zero-padded) expansion of r . Thus,

$$c_{10}(n) = c_{10}(q) + c_{10}(r) \geq 1 + (k - 1) = k.$$

This completes the proof. □

Corollary 1. *Let a be a positive integer that is divisible by 2 but not divisible by 10. Then $c_{10}(a^n) \geq \log_4(n)$ for all $n \geq 1$. In particular, $\lim_{n \rightarrow \infty} c_{10}(a^n) = \infty$.*

Proof. Let $e(k) = 4^{k-1}$ for $k \geq 1$. This sequence satisfies $e(1) \geq 1$ and

$$2^{e(k)} > 10^{e(k-1)}$$

for all $k \geq 2$.

Let $n \geq 4$ be a positive integer, and let $k = \lceil \log_4 n \rceil$, so that $4^{k-1} < n \leq 4^k$. Then a^n is divisible by 2^n , so a^n is also divisible by $2^{e(k)}$. But a^n is not divisible by 10.

Therefore, $c_{10}(a^n) \geq k \geq \log_4(n)$, by Theorem 1. □

4. GENERALIZING TO OTHER BASES

Before extending the arguments of the previous section, we first situate our results in the broader context of earlier work on digital sums of powers. In a foundational

paper from 1973, Senge and Straus [7, Theorem 3] showed that for integers $a \geq 1$ and $b \geq 2$,

$$\lim_{n \rightarrow \infty} c_b(a^n) = \infty \iff \frac{\log a}{\log b} \text{ is irrational.}$$

Their result provides a qualitative criterion for unbounded digit growth, but it does not yield any explicit lower bound.

Subsequently, Stewart [9, Theorem 2] obtained the first general quantitative estimate. Under the same hypothesis of irrationality of $\log(a)/\log(b)$, he proved that

$$c_b(a^n) > \frac{\log n}{\log \log n + C} - 1$$

for all $n > 4$, where C depends only on a and b . This bound is extremely general but grows more slowly than logarithmic.

In this section we prove a logarithmic lower bound for $c_b(a^n)$ under a set of hypotheses that are stronger than Stewart's but still hold in many natural situations. Our approach proceeds in two steps: first we establish a structural digit-sum bound for integers forced to be divisible by powers of a but not by b , and then we apply it to a^n itself under an additional irrationality condition. The first step (Theorem 2 below) generalizes the corresponding base-10 argument from the previous section.

Theorem 2. *Let a, b be integers such that $2 \leq a < b$ and a divides b . Let $(e(k))$ be a sequence of integers such that $e(1) \geq 1$ and $a^{e(k)} \geq b^{e(k-1)}$ for all $k \geq 2$. If $a^{e(k)}$ divides n and $b \nmid n$, then $c_b(n) \geq k$.*

Proof. Follow the proof of Theorem 1, but replace 2 with a where appropriate, and replace 10 with b . \square

Theorem 3. *Let a, b be integers such that $2 \leq a < b$ and a divides b . Suppose that N is divisible by a^n but not b . Then there exists $C > 0$, depending only on a and b , such that*

$$c_b(N) > C \log n$$

for n sufficiently large. Indeed, we can choose any $0 < C < (\log(\log b / \log a))^{-1}$.

Proof. Let $r = \log b / \log a$, and define (e_k) by $e_1 = 1$ and $e_k = \lceil r e_{k-1} \rceil$ for $k \geq 2$. It is routine to verify that (e_k) satisfies the conditions of Theorem 2.

Then,

$$\begin{aligned} e_2 &< r + 1, \\ e_3 &< r^2 + r + 1, \\ e_4 &< r^3 + r^2 + r + 1, \end{aligned}$$

and for all $k \geq 1$,

$$(1) \quad e_k < \sum_{i=0}^{k-1} r^i < \frac{r^k}{r-1}.$$

Now suppose that n is an integer greater than $\frac{r}{r-1}$, and let

$$k = \left\lfloor \frac{\log((r-1)n)}{\log r} \right\rfloor.$$

Then

$$1 \leq k \leq \frac{\log((r-1)n)}{\log r},$$

which implies that

$$n \geq \frac{r^k}{r-1}.$$

Therefore $n > e_k$ by (1), hence $c_b(N) \geq k$ by Theorem 2.

Choose C so that $0 < C < (\log r)^{-1}$. Then

$$\left\lfloor \frac{\log((r-1)n)}{\log r} \right\rfloor > C \log n$$

for n sufficiently large, which implies that $c_b(N) > C \log n$. \square

The following lemma allows us to relax the condition that b does not divide a^n .

Lemma 1. *Let $a, b \geq 2$ be integers such that $\log a / \log b$ is irrational. Suppose that $a^n = b^r u$. Then there exists a prime factor p of a , and $C > 0$ depending only on a and b , such that $\nu_p(u) \geq Cn$.*

Proof. Since $\log a / \log b$ is irrational, there exist primes p and q such that

$$(2) \quad \nu_p(a)\nu_q(b) - \nu_q(a)\nu_p(b) > 0.$$

In particular, $\nu_p(a) \geq 1$ and $\nu_q(b) \geq 1$.

By comparing the valuations of a^n with respect to p and q , we obtain

$$(3) \quad n\nu_p(a) = r\nu_p(b) + \nu_p(u)$$

and

$$(4) \quad n\nu_q(a) \geq r\nu_q(b).$$

Combining (3) and (4) yields

$$(5) \quad \nu_p(u) \geq n\nu_p(a) - n\frac{\nu_q(a)}{\nu_q(b)}\nu_p(b) = Cn,$$

where

$$C = \frac{\nu_p(a)\nu_q(b) - \nu_q(a)\nu_p(b)}{\nu_q(b)}.$$

Finally, $C > 0$ by (2). □

We now come to the main result of this section.

Theorem 4. *Let $a \geq 2$ and $b \geq 2$ be integers. Let d be the smallest factor of a such that $\gcd(a/d, b) = 1$, and suppose that $\log(d)/\log(b)$ is irrational. Then $c_b(a^n) > C \log n$ for all $n \geq 1$, where $C > 0$ depends only on a and b .*

Proof. Let $a^n = b^r u$, where $b \nmid u$. If $\log d / \log b$ is irrational, then $\log a / \log b$ is also irrational; so Lemma 1 implies that there exists a prime factor p of a , and $C' > 0$ depending only on a and b , such that $\nu_p(u) \geq C'n$.

But p also divides d , since $\gcd(p, a/d) = 1$. Therefore, $c_b(u) > C \log n$ for some $C > 0$ by Theorem 3.

Finally, $c_b(u) = c_b(a^n)$, since m and a^n have the same digit expansion, apart from trailing zeros. □

5. DIGITAL SUMS OF FACTORIALS AND LCMs

The results of the previous section showed how information about the prime-power divisibility of an integer can force its base- b digital sum to grow at least logarithmically. Although we now turn to a different family of integers, namely $n!$ and the least common multiple $\Lambda_n = \text{lcm}(1, \dots, n)$, the same guiding principle remains: multiplicative structure can impose strong, and often very elementary, constraints on possible base- b representations.

In contrast with the situation for a^n , where prime-power divisibility played a central role, the key structural feature for factorials and LCMs is that both $n!$ and Λ_n are

divisible by large integers of the form $b^r - 1$. This observation leads immediately to logarithmic lower bounds on their digital sums, provided one has an effective way to bound the digital sum of a multiple of $b^r - 1$.

The following lemma, originally proved by Stolarsky [10] for base 2 and extended to general bases by Balog and Dartyge [1], supplies exactly such a tool.

Lemma 2. *Let $m, r \geq 1$ and $b \geq 2$ be integers. If m is divisible by $b^r - 1$, then $s_b(m) \geq (b - 1)r$.*

Proof. Write the base- b expansion of m as a concatenation of r -digit blocks, so that

$$m = \sum_{i=0}^{k-1} B_i b^{ri}, \quad 0 \leq B_i < b^r, \quad B_{k-1} \geq 1.$$

Define the *block-sum* operator G by

$$G(m) = \sum_{i=0}^{k-1} B_i.$$

Observe that $G(m) \equiv m \pmod{b^r - 1}$, since $b^r \equiv 1 \pmod{b^r - 1}$. Also, $G(m) < m$ for $m \geq b^r$, and $G(m) = m$ for $0 \leq m < b^r$.

Iterate G on m : define $m_0 = m$ and $m_{t+1} = G(m_t)$. By the observations above, (m_t) is a sequence of positive multiples of $b^r - 1$, which is strictly decreasing while its terms exceed $b^r - 1$. Therefore, the sequence must eventually reach $b^r - 1$, which is the unique positive multiple of $b^r - 1$ that is less than b^r .

Since s_b is subadditive,

$$s_b(G(m)) \leq \sum_{i=0}^{k-1} s_b(B_i) = s_b(m).$$

Therefore,

$$s_b(m) \geq s_b(b^r - 1) = (b - 1)r.$$

□

This lemma has an immediate consequence for factorials and LCMs. If $n \geq b^r - 1$, then both $n!$ and Λ_n are divisible by $b^r - 1$, and hence

$$s_b(n!) \geq (b - 1)r, \quad s_b(\Lambda_n) \geq (b - 1)r.$$

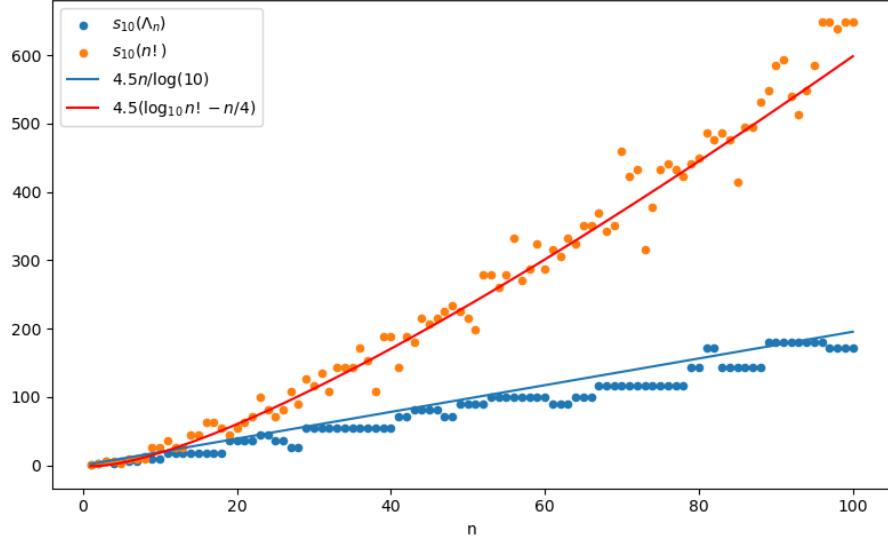

FIGURE 3. Scatter plot of the digital sums of $n!$ and Λ_n for $n \leq 100$, together with their conjectured approximations.

Since one may choose $r = \lfloor \log_b(n+1) \rfloor$, this yields lower bounds of the form

$$s_b(n!) > C \log n, \quad s_b(\Lambda_n) > C \log n$$

for some constant $C > 0$ depending only on b .

Stronger bounds are known. In 2015, Sanna [6] used this lemma, together with more advanced methods, to prove that

$$s_b(n!) > C \log n \log \log \log n$$

for all integers $n > e^e$ and all $b \geq 2$, where C depends only on b . The same estimate holds for $s_b(\Lambda_n)$. Our interest here is not to compete with the best known results, but rather to show that simple divisibility arguments already imply logarithmic growth.

We conjecture that $s_b(n!) \asymp n \log n - n$ and $s_b(\Lambda_n) \asymp n$, but this remains to be proved. See Figure 3.

6. DIGITAL SUMS OF POWERS: THE GENERAL CASE

In this final section, we prove that the number of nonzero digits in the base- b expansion of a^n tends to infinity as $n \rightarrow \infty$, provided that $\log(b)/\log(a)$ is irrational. This result appears in earlier work of Senge and Straus [7] and Stewart [9], but we present an argument that we hope is more accessible.

The irrationality condition is necessary. Indeed, if $\log(a)/\log(b) = r/s \in \mathbb{Q}$, then

$$a^{ns} = b^{nr}$$

for every integer n , so a^{ns} has only one nonzero digit in base b .

We may assume without loss of generality that $a < b$. If not, replace b with b^r , where $b^r > a$. Since $c_{b^r}(n) \geq c_b(n)/r$, this replacement does not affect the order of growth.

Recall that a nonzero algebraic number $\alpha \in \mathbb{C}$ is a root of a unique irreducible integer polynomial P with positive leading coefficient and coprime coefficients. The *degree* of α is equal to the degree of P , and the *height* of α is the maximum of the absolute values of the coefficients of P . A rational integer has degree 1 and height equal to its absolute value.

Our proof relies on a version of Baker's theorem on linear forms in logarithms, which we state without proof.

Theorem 5. [2, p. 23] *Let $\alpha_1, \dots, \alpha_n$ be nonzero algebraic numbers with degrees at most d . Suppose that $\alpha_1, \dots, \alpha_{n-1}$ and α_n have heights at most $A' \geq 4$ and $A \geq 4$ respectively. Let β_1, \dots, β_n be integers of absolute value at most $B \geq 2$. If*

$$\Lambda = \beta_1 \log \alpha_1 + \dots + \beta_n \log \alpha_n \neq 0,$$

there exists $C > 1$, depending only on n , d , and A' , such that

$$|\Lambda| > C^{-\log A \log B}.$$

See [4] for an explicit lower bound.

Baker's theorem gives effective lower bounds on linear forms in logarithms of algebraic numbers. In our context, it guarantees that the expression in (10) below cannot be too small, which limits how well powers of a can be approximated by powers of b .

The next lemma deals with the possibility that some power of a might be divisible by b .

Lemma 3. *Let $a, b \geq 2$ be integers with $\log(a)/\log(b)$ irrational. Then there exist C and C' , depending only on a and b , such that whenever*

$$a^n = b^r u,$$

we have

$$Cn \leq \log u \leq C'n.$$

In other words, $\log u \asymp n$.

Proof. By Lemma 1, there exists a prime factor p of a , and $C_1 > 0$ depending only on a and b , such that $\nu_p(u) > C_1 \log n$ for all n . Therefore, $u \geq p^{C_1 n}$ and $\log u \geq Cn$ for $C = C_1 \log p$. On the other hand, $\log u \leq C'n$ for $C' = \log a$, since $u \leq a^n$. \square

We now prove the main theorem.

Theorem 6. *Let $a, b \geq 2$ be integers with $a < b$, and suppose that $\log(a)/\log(b)$ is irrational. Then there exists $C > 0$, depending only on a and b , such that*

$$c_b(a^n) > \frac{\log n}{\log \log n + C}$$

holds for all sufficiently large n .

Proof. Let

$$a^n = b^m (d_1 b^{-m(1)} + \cdots + d_k b^{-m(k)}),$$

where $m = \lceil \log_b a^n \rceil$, $k = c_b(a^n)$, $d_i \in \{1, \dots, b-1\}$, and

$$1 = m(1) < \cdots < m(k) \leq m.$$

That is, d_1, \dots, d_k are the nonzero digits of a^n in base b , and $m(1), \dots, m(k)$ are their positions when the digits are numbered from left (most significant) to right (least significant).

Fix $i \in \{1, \dots, k-1\}$. We estimate the ratio $m(i+1)/m(i)$, which will ultimately bound k .

Define

$$\begin{aligned} q &= b^{m(i)} (d_1 b^{-m(1)} + \cdots + d_i b^{-m(i)}), \\ r &= b^m (d_{i+1} b^{-m(i+1)} + \cdots + d_k b^{-m(k)}), \end{aligned}$$

so that

$$a^n = b^{m-m(i)} q + r.$$

From the base- b expansion we obtain the bounds

$$\begin{aligned} b^{m-1} &\leq a^n \leq b^m, \\ b^{m(i)-1} &\leq q \leq b^{m(i)}, \\ b^{m-m(i+1)} &\leq r \leq b^{m-m(i+1)+1}. \end{aligned}$$

Consequently,

$$(6) \quad b^{-m(i+1)} < a^{-n} r < b^{-m(i+1)+2},$$

which implies that

$$(7) \quad \frac{m(i+1)-2}{m(i)} \leq \frac{-\log(a^{-n}r)}{\log q} \leq \frac{m(i+1)}{m(i)-1}$$

provided that $q \geq 2$ and $m(i) \geq 2$.

If $m(i) \geq 3$ (and $m(i+1) \geq 4$) then

$$(8) \quad \frac{m(i+1)-2}{m(i)} \geq \frac{1}{2} \frac{m(i+1)}{m(i)}, \quad \frac{m(m+1)}{m(i)-1} \leq \frac{3}{2} \frac{m(i+1)}{m(i)},$$

hence

$$(9) \quad \frac{1}{2} \frac{m(i+1)}{m(i)} \leq \frac{-\log(a^{-n}r)}{\log q} \leq \frac{3}{2} \frac{m(i+1)}{m(i)}.$$

Now set

$$(10) \quad \Lambda = \log(a^{-n}b^{m-m(i)}q) = -n \log a + (m-m(i)) \log b + \log q.$$

Then (since $a^{-n}r < 1/2$)

$$|\Lambda| = -\log(1-a^{-n}r) < 2a^{-n}r.$$

We apply Baker's theorem to the linear form in (10). There are two cases, depending on the size of q .

Case 1: $q < b^2$, or equivalently, $m(i) \leq 2$.

In this case, we can apply Baker's theorem with $A = b^2$ and $B = n$ to obtain

$$|\Lambda| > C_1^{-\log n} = n^{-C_2}$$

for some constant $C_2 > 0$ depending only on a and b . Thus,

$$a^{-n}r > n^{-C_2},$$

and hence, for n sufficiently large,

$$b^{-m(i+1)+2} > n^{-C_2},$$

which implies that

$$m(i+1) < C_3 \log n$$

for some constant $C_3 > 0$ depending only on a and b .

Since $m(i) \geq 1$, we also have

$$\frac{m(i+1)}{m(i)} < C_3 \log n.$$

Case 2: $q > b^2$, or equivalently, $m(i) \geq 3$.

In this case, we can apply Baker's theorem with $A = q$ and $B = n$ to obtain

$$|\Lambda| > C_4^{-\log q \log n}$$

for some $C_4 > 1$ depending only on a and b . Thus,

$$a^{-n}r > C_4^{-\log q \log n},$$

and hence, for n sufficiently large,

$$(11) \quad \frac{-\log(a^{-n}r)}{\log(q)} < C_5 \log n$$

for some $C_5 > 0$ depending only on a and b .

Combining (9) and (11) gives

$$\frac{m(i+1)}{m(i)} < C_6 \log n.$$

for some $C_6 > 0$ depending only on a and b .

In either case, we have

$$\frac{m(i+1)}{m(i)} < C_7 \log n, \quad C_7 = \max(C_3, C_7).$$

Summing the logarithms of these ratios,

$$\log m(k) = \sum_{i=1}^{k-1} \log \left(\frac{m(i+1)}{m(i)} \right)$$

which yields

$$(12) \quad \log m(k) < (k-1)(\log \log n + C_8).$$

Write a^n as $b^{m-m(k)}u$, where

$$b^{m(k)-1} < u < b^{m(k)}.$$

Thus $m(k) \asymp \log(u)$, and $\log(u) \asymp n$ by Lemma 3, so

$$(13) \quad \log m(k) = \log n + O(1).$$

Therefore, (12) and (13) imply that

$$k > \frac{\log n}{\log \log n + C}$$

for all sufficiently large n , as required. \square
